INDIVIDUAL REPORT

I. Who am I in this project?

LE BAO NGOC

LEAD DEVELOPER

Frontend Development, Gameplay Integration & AI-Assisted Implementation

1. My role in this project

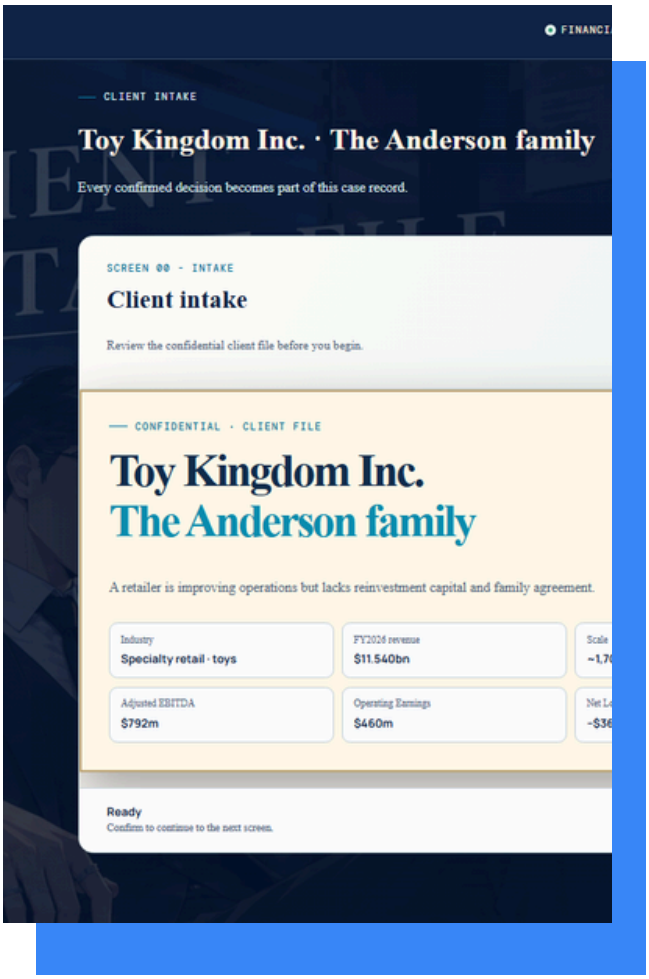

My primary responsibility was to develop and refine MEDIFIN's interactive game interface while ensuring consistency between the visual design, storyline, player decisions, and underlying game mechanics. I also worked on two versions of MEDIFIN: medifin-v2 and medifin-v4.

My contribution involved identifying problems, translating them into detailed implementation requirements, directing code revisions, and reviewing whether the changes aligned with the intended gameplay.

I. Who am I in this project?

2. Personal highlight

The most significant aspect of my work was addressing inconsistencies between the player's decisions, subsequent story developments, and the game's visual presentation.
For example, in Round 9, the original gameplay allowed players to directly decide whether David agreed with their proposal. I identified that this contradicted the purpose of the communication decisions in earlier rounds. I therefore proposed changing the mechanic so that David's response would depend on the player's previous interactions rather than being selected manually.

This example also shaped how I approached other revisions. A player should not be given an answer or asked an irrelevant follow-up solely because a certain screen exists; the screen must be justified by the decisions and information available at that point.

II. What did I build?

Frontend implementation and narrative flow

My frontend contributions covered Scenes 1, 6, 8, 10, the Governance & Family storyline, Scene 14, and the final Summary screen.

Gameplay logic and interaction fixes

Another major part of my contribution was identifying situations where game interactions did not behave consistently with previous decisions.

UI/UX improvements

I reviewed several interface issues that affected readability: white text placed on pale backgrounds, inconsistent fonts across question and option components, incomplete question wording, and oversized selection cards. I requested consistent typography, clearer player instructions, and English language throughout the application

Frontend and backend integration

I defined the integration requirements to retain the established interface, typography, character designs, and round presentation while incorporating the latest backend logic and scoring framework.

III. How can you verify my work?

1. Evidence of contribution

My contributions can be demonstrated through the MEDIFIN source-code versions, Codex implementation conversations, GitHub revision history, Figma references, and before-and-after interface screenshots.
The strongest evidence would include comparisons of the Round 2 document popup, Governance & Family branch, Round 9 agreement mechanism, Round 11 follow-up layout, and final Summary screen.
These examples show how individual issues were identified, translated into implementation requirements, and addressed through iterative development.

2. How my work connects to the final product

My work connects directly to the player's experience throughout the game. The scene development establishes how players receive information, the interaction changes determine when information becomes available, and the gameplay corrections ensure that subsequent events remain consistent with earlier decisions.
The integration work also connects the visual layer of MEDIFIN with its updated decision-making and scoring systems, which is essential for delivering a coherent playable product.

IV. What did I learn?

1. Lessons learned

Through this project, I learned that developing an interactive financial simulation requires more than producing functional interfaces.
A small change to a player decision may affect later dialogue, branching scenarios, information availability, and the final outcome. I learned to consider these dependencies instead of treating each screen as an independent component.
I also became more effective at working with AI coding tools. Rather than requesting broad changes such as "fix this screen," I learned to define the affected round, expected behavior, trigger condition, visual requirements, and relationship with previous decisions.

2. Challenges and how I addressed them

The greatest challenge was maintaining consistency while MEDIFIN's design and gameplay mechanics were evolving simultaneously.
Some issues were visual, such as inconsistent typography and poorly sized components. Others were structural, such as conditional scenes appearing at incorrect points or players being asked questions that contradicted their earlier actions.
I addressed these issues by breaking them into smaller, testable requirements and refining Codex instructions through multiple iterations.
A further challenge was integrating two versions with different strengths. This required identifying which elements should be retained from each version and establishing clear priorities between visual consistency and updated gameplay logic.

V. What would I tell the future team?

My main recommendation is to establish a shared reference for game states, decision dependencies, scene transitions, and scoring rules before implementing the interface. Each scene should have a clearly defined trigger, required information, and expected next step. When a decision is changed, the team should also review all subsequent rounds that depend on it.

I would also recommend maintaining one primary development version instead of allowing the frontend and backend to evolve into separate products.

Finally, although AI coding tools can accelerate development, they are most effective when developers understand the intended behavior, provide precise requirements, and verify the resulting implementation against the actual player journey.

Final reflection

For me, the most valuable contribution was learning to connect interface development with realistic financial decision-making. A successful MEDIFIN experience requires visual clarity, reliable state dependencies, and meaningful feedback—not merely a sequence of attractive screens.

APPENDIX

FRONTEND SCENE AND NARRATIVE SCOPE	
Scenes 1, 6, 8, 10	Create or refine the specified interactive scene layouts and their round-to-round presentation.
Governance & Family	Build the dedicated storyline; show three additional Figma-based screens when the relevant Round 2 file is selected.
Scene 14	Implement the scene interface and keep the navigation consistent with the surrounding consultation.
Before Round 2	Introduce the client's document set and the three-file review constraint; Next starts Round 2.
Before Round 4	Present the CFO's audited consolidated financial statements; Next starts Round 4.
Before Round 5	Present contextual client dialogue for all paths; retain Governance & Family information where applicable.
Before Rounds 8 / 11	Insert Screen 11 and Screen 15 respectively, both advanced using Next.
Follow-up	Introduce client-message selection and character imagery within follow-up options.
Summary	Refine the results design, preserve readability, and apply the specified high-score visual treatment.

BUG-FIX AND UX IMPROVEMENT LOG		
R2: popup timing	Reveal the selected document only after Record Question; enlarge the popup.	Avoid premature disclosure.
R5: inconsistent intro	Display the general Round 5 transition across all routes.	Preserve a coherent flow.
R9: David consent	Remove the player-selected agreement; derive the response from earlier dialogue.	Restore decision causality.
Follow-up mismatch	Revise conditional questions when players retain both earlier choices.	Prevent invalid prompts.
R11: overcrowded UI	Remove redundant briefing/consent text; scale down four option cards.	Improve clarity.
Global text issues	Fix low contrast and inconsistent type; rewrite labels as full instructions.	Increase readability.
Language mismatch	Translate player-facing content consistently into English.	Remove language switching.
Summary mismatch	Reuse medifin-v3 results clarity; change doctor artwork at high scores.	Improve feedback UX.
